

CSCE 2110
Fall 2015
Program 2 – Basic Undirected Graph
100 Points

Date Due: Wednesday, October 7, 2015 (Start of Class)

Programs 2, through 4 for this class will serve as an incremental implementation of a Road Atlas and Driving Distance Calculator. User input will be in the form of commands. The user must be able to input commands via the command line OR from a file in a CSV format. **BOTH input methods must be available to the user.** This format will allow the easy creation of a large number of inputs quickly without the need for a long series of prompts and responses. The commands used in the CSV file are identical to the command line commands EXCEPT, of course, each field of the command in a CSV file is separated by a comma. Also, neither the command "file" nor the command "Quit" will be issued from a CSV file. These are NOT "error conditions" that must be handled ... it is just a promise from the instructor. Once all commands in a given command file have been processed, the program returns to the interactive mode with a command prompt.

Program 2 must build an Undirected Graph from user input. Nodes are created first. For the sake of simplicity, all nodes will be named with a SINGLE LETTER (A-Z) for a total of 26 possible nodes. Edges are then created between existing nodes. Once created, both nodes and edges can be deleted. Your program can handle the graph either as an ADJACENCY MATRIX or as an ADJACENCY LIST. The only restriction is that your entire Team must use the same method, since the final program in the class will be submitted as a group project (one submission per team).

When the program is executed, it begins with a command prompt: **cmd>**. Your Program must implement the following commands:

NOTE: The commands shown below are the commands that should be implemented. Do NOT use an indexed list of commands for command selection. Each command and its respective parameter(s) should be input on a single line. Missing parameters should result in a prompt to the user to provide the missing data. Missing parameters in the case of file-input commands simply results in an error message. There will be NO INTENTIONAL ERRORS in a Command File. If you encounter an error via the Command File, immediately notify Dr. Burke by email.

1. **Add a node to the graph.** The user provides a NAME for a node. If the NAME does not exist in the graph, the node is added and acknowledged. If the NAME already exists in the graph, an error message is issued.
 - **FORMAT: node add <name> ==>**
 - **EXAMPLE: node add A**
 - Return: **ADDED: NODE A**
 - Error: If the "name" is a duplicate of one already in the graph, print the following error message to the screen: ***** ERROR *** DUPLICATE NODE: A**
2. **Delete a node from the graph.** The user provides a NAME for a node that should be deleted.
 - **FORMAT: node delete <name>**
 - **EXAMPLE: node delete A**
 - Return: **DELETED: NODE A**
 - Error: If the "name" is NOT in the graph, print the following error message to the screen: ***** ERROR*** NODE NOT FOUND FOR DELETION: A**
 - The deletion of a node may cause the deletion of 1 or more edges. Report EACH EDGE that is automatically deleted as a result of a node deletion.
 - **EDGE AUTO REMOVED BY NODE DELETION: A-B**
 - **EDGE AUTO-REMOVED BY NODE DELETION: A-D**
3. **Search for a node in the graph.** The user provides a NAME of a node for which to search.
 - **FORMAT: node search <name>**
 - **EXAMPLE: node search A**
 - Return: **NODE A: FOUND**
NODE A: NOT FOUND
4. **Add an edge to the graph.** The user provides TWO NODE NAMES as the end points of a new edge. If the NAMES exist in the graph without an edge between them, the edge is added and acknowledged. If the EDGE already exists in the graph, an error message is issued. Likewise, if EITHER NODE does not exist, an error message is issued. **The graph is undirected, so adding A-B also must add B-A.**

- **FORMAT: edge add NODE1 NODE2**

- **EXAMPLE: edge add A B**

- Return: **ADDED: EDGE A-B**
ADDED: EDGE B-A

- Error: If the EDGE is a duplicate of one already in the graph, print the following error message to the screen: ***** ERROR *** EDGE NOT DELETED * DUPLICATE: A-B**
- Error: If EITHER node does not exist in the graph, print the following error message to the screen: ***** ERROR *** NODE A: NOT FOUND**
-OR- * ERROR *** NODE B: NOT FOUND**

Note that a node CAN have an edge back to itself (e.g. edge add A A)

- 5. Delete an edge from the graph.** The user provides TWO NODE NAMES as the end points of an edge to be deleted. If the NAMES exist in the graph with an edge between them, the edge is deleted and acknowledged. If the requested edge does NOT exist in the graph, an error message is issued.

- **FORMAT: edge delete NODE1 NODE2**

- **EXAMPLE: edge delete A B**

- Return: **DELETED: EDGE A-B**
- Error: If the EDGE does not exist in the graph, print the following error message to the screen: ***** ERROR *** EDGE DOES NOT EXIST FOR DELETION: A-B**

- 6. Print the Graph in Adjacency Matrix Format.**

- **FORMAT: print matrix ***** ALPHABETIC ORDER by Node Names on axes *******

- 7. Print the Graph in Adjacency List Format.**

- **FORMAT: print list ***** Print in ALPHABETIC ORDER by Node Names *******

- 8. Execute command from a Command File.** Commands can be stored in a CSV file to be executed one at a time, just like they were being input from the command line. The format of the commands is identical to the descriptions above EXCEPT that the individual fields are separated by commas. Note that it is also possible that there may be extra commas at the end of some or ALL of the instruction lines. Your program must be able to tolerate (ignore) these extraneous commas at the end of the lines.

- **FORMAT: file \home\pwb0013\csce2110\program2\data\Prog2_Test.csv**

- 9. Quit execution.**

- **FORMAT: quit**

PROGRAM SUBMISSION:

Submit INDIVIDUAL program files with CSCE-2100 Specified Filenames (**NO *.zip files, NO *.tar files, NO *.rar files**) to BlackBoard before the due date. The file naming convention must conform to the standard as described in the instructions for Program 1. Specifically:

LxxF_10_P2_yyy.cpp -OR- *.h

where: "Lxx" is the first 3 character of your LAST name.

"F" is the first character of your FIRST name.

"10" identifies the assignment is for CSCE2110.

"P2" is the identifier for this assignment (P2=Program 2).

"yyy" is any other text (descriptive name) that you choose as your unique filename(s).

EXAMPLE: BurP_10_P2_Main.cpp

Multiple submissions of one or all of your files will be allowed. Your program files will all be extracted to a single UNIX (csexx.cse.unt.edu) subfolder and will be compiled with the command: **make**

Once compiled, we will execute with command: **make run**

You are allowed AND ENCOURAGED to discuss the details of this assignment with your Teammates. Programs 2-4 will be submitted by each person. Program 4 will be a single submission for the entire Team. You should be working together so that each individual understands exactly how this program works. I also encourage the reuse of code, even from books or the internet. You **MUST** specify the source if you are reusing code, but why reinvent the wheel? Instead, start with something that works ... that YOU UNDERSTAND ... and spend your time modifying that code to do your bidding! That is not cheating ... that is working smart.

We will be discussing the overall project in class throughout the semester. Use these discussions to shape your code into something that can be reusable with minimal effort for the follow-on functionality. Remember to use functions to do most of the work to isolate changes in input/output/storage to single functions, instead of having to rewrite all of the code. Failure to submit to BlackBoard ON-TIME will result in a score of ZERO for the assignment.
